

--- Chapter One ---

# *Introduction*

The aim of this workbook is to help marine biologists familiarise themselves with using GIS in their research. To do this, it uses a Task Oriented Learning (TOL) approach, first introduced in *An Introduction To Using GIS In Marine Biology*, to provide five exercises based around creating maps for inclusion in reports and publications. As such, it does not represent a stand alone GIS book and is meant to act as a companion guide to the original book rather than to replace it in any way. It does not provide any background information on using GIS as this has already been covered within *An Introduction To Using GIS In Marine Biology* itself. Instead, it simply provides instructions for how to do the exercises themselves.

Thus, this workbook is primarily aimed at those who have read some or all of *An Introduction To Using GIS In Marine Biology*. If you have not already done so, it is recommended that at a minimum you read chapters seven (*Translating biological tasks into the language of GIS*), eleven (*How to use the 'How To...' sections of this book*) and twenty (*How to combine instruction sets for basic tasks to create instruction sets for more complex tasks*) of *An Introduction To Using GIS In Marine Biology* before working through these exercises. It will also help if you are familiar with the basics of GIS (chapter two), common concepts and terms in GIS (chapter three), the importance of projections, coordinate systems and datums (chapter four), types of GIS data layers (chapter five), starting a GIS project (chapter six) and how to set up a GIS project (chapter thirteen). Finally, it is worth at least flicking through chapters thirteen to nineteen to familiarise yourself with how instruction sets are laid out using the TOL approach introduced in *An Introduction To Using GIS In Marine Biology*.

This supplementary workbook uses ArcGIS 10.2 software to illustrate how these tasks should be done. However, similar processes are likely to be used to achieve similar outcomes in other GIS software.

The exercises provided in this book are designed to be worked through in a sequential manner. This is because the same data sets are used throughout and you may need to use some of the data layers generated in earlier exercises for later ones. In addition, the exercises lead on from each other in a manner that develops your familiarity with creating maps in GIS, so increasing the benefit of conducting the exercises in the sequence provided. For example, while the first exercise deals with creating a map template for a specific project which can be used repeatedly to ensure all your maps look similar, later exercises involve adapting this template to create more complex maps.

The exercises are provided using the same flow diagram-based format introduced in the 'How To...' reference guide section of *An Introduction To Using GIS In Marine Biology*, and specifically in chapter twenty which outlined how to combine individual instruction sets to work out how to do more complex tasks. This means that for each exercise, you will first find an outline of what will be achieved by the end of it, why it is useful for marine biologists to be able to do this and what data layers you will need to start with. You will then find a summary flow diagram which will detail the order which individual instruction sets for basic tasks must be done. Finally, you will find a set of numbered instruction sets based on those provided in *An Introduction To Using GIS In Marine Biology*. These have been customised to make them specific to the data sets used for each example. In order to complete a specific exercise, you will need to work through each of these instruction sets in the order given in the summary flow diagram. In order to allow you to know whether you are progressing correctly, figures will be provided at regular intervals which will show you what the contents of the MAP window, LAYOUT window, TABLE OF CONTENTS window and/or TABLE window should look like at that specific stage.

The data sets used in each exercise can be downloaded from [www.gisinecology.com/books/marinebiologysupplementaryworkbook](http://www.gisinecology.com/books/marinebiologysupplementaryworkbook).

**NOTE:** The instruction sets provided here are for training purposes only, and are only meant to be an aid to learning how to use GIS in marine biological research. While every effort has been made to ensure that these instructions are complete and error-free, they come with no guarantee of accuracy and, as with all technical books, some errors may have slipped through undetected. Whenever I become aware of any such issues, I will post

corrections on [www.GISinEcology.com/books/marinebiology/corrections](http://www.GISinEcology.com/books/marinebiology/corrections) rather than waiting to correct them in the next edition of this book. Therefore, before doing any of the exercises in this book, you should check this webpage to see if any corrections have been posted. In addition, it is important to realise that there is no guarantee that these instructions will produce the desired outcome in every circumstance. As a result, if you are using the instruction sets provided here to learn how to do critical tasks, it is essential that you check (and then double check) that they work for your given circumstances rather than blindly following them without thinking. The author will not be responsible for any errors which occur because of the application of these instruction sets to real world situations.

**NOTE:** As with many things in GIS, there may be more than one way to do the exercises outlined in this book. The instructions presented here will work for the data set provided and for the exercises outlined in this book. They should also work in most other circumstances. However, if you find an alternative way to do them which works for your data, or if you have someone who can show you how to do them in another way, feel free to do them differently.
